

## Project Overview

The project is a website/app that connects people with similar interests by asking the users for their interests then adding them to a map then users can start seeing users with similar interests near them.

The app goal is not dating but it's about connecting people and helping people make connections and good friends. If they end up dating then it's not a problem.

Target group is all kinds of people.

The issue resolved here is helping people meet each other.

I plan to build the backend API then build a separate front end app.  
I plan to have an MVP then show it to others then possibly make a beta and pitch the idea to possible investors.

The plan is build the backend in the next 2 weeks then start working on a very simple version of the front end with least amount of features then start adding more and more once i have more time.

The technology stack is Golang for backend and using gearbox framework (a framework i am a maintainer of and started with a friend of mine)

Postgresql for Database and AWS for hosting.

For front end i am planning to use Vue.js with [capacitorjs](#) which would allow me to compile my normal vue.js web app into a cross platform app that can run on Android and IOS as well with minimum amount of code changes.
